# KPP in periodic media

Consider the KPP equation in a periodic medium:

$$\begin{aligned} \text{(KPP)} \quad & \partial_t u(t, x) = \nabla(A(x)\nabla u(t, x)) + f(x, u(t, x)) \\ & t > 0, \quad x \in \mathbb{R}^n \quad u(0, x) = u_0(x) \geq 0 \end{aligned}$$

$A, b, f$  are  $C^1$  and 1-periodic in each direction  $x_i$

$A(x) \in \mathbb{R}^{n \times n}$  positive definite, not necessarily symmetric

$f(x, 0) = f(x, 1) = 0$

$f(x, u)/u$  is decreasing for  $u > 0$

$\partial_u f(x, 0) =: \mu(x) > 0$  for  $0 < u < 1$

e.g.  $f(x, u) = \mu(x)u(1 - u)$

Classical case  $n = 1$ :  $u_t = Au_{xx} + \mu u(1 - u)$

## Travelling waves

A travelling wave solution in direction  $e \in \mathbb{R}^n$ ,  $|e| = 1$  with speed  $c$  satisfies with  $\xi = ct + e \cdot x \in \mathbb{R}$ :

$$u(t, x) = U(\xi, x), \quad U(\xi, x) \text{ is periodic w.r.t. } x_j$$

$$\begin{aligned} \text{(TW)} \quad c\partial_\xi U(\xi, x) &= (\nabla + e\partial_\xi)(A(x)(\nabla + e\partial_\xi)U(\xi, x)) + f(x, U(\xi, x)) \\ U(-\infty, x) &= 0, \quad U(\infty, x) = 1 \end{aligned}$$

We need the following linear operator.

With  $\mu(x) = \partial_u f(x, 0)$  and  $\lambda \geq 0$  let

$$(L_\lambda \phi)(x) = \nabla(A(x)\nabla\phi(x)) + \mu(x)\phi(x)$$

$$\phi(x)e^{-\lambda e \cdot x} \text{ is 1-periodic}$$

Due to the last condition  $L_\lambda$  is not selfadjoint !

Let  $k(\lambda)$  be the principal eigenvalue with corresponding eigenfunction  $\phi(x) > 0$ .

## Theorem (Berestycki, Hamel '02)

*A travelling wave exist iff*

$$c \geq c(e) := \min_{\lambda > 0} \frac{k(\lambda)}{\lambda}$$

**Explanation:** Let  $(U(\xi, x), c)$  be a travelling wave.

$$U(\xi, x) \sim e^{\lambda \xi} v(x), \quad \xi \rightarrow -\infty \quad \lambda > 0, \quad v \text{ periodic}$$

Then  $\phi(x) := e^{\lambda e \cdot x} v(x) > 0$  satisfies

$$L\phi(x) = \lambda c \phi(x)$$

Hence  $c = \frac{k(\lambda)}{\lambda}$ . Construction of upper and lower solutions shows, that every  $c$  in the range of  $\frac{k(\lambda)}{\lambda}$  occurs.  
How does  $c(e)$  depend on  $A, \mu, e$  ?

# Asymptotic Spreading

Consider an initial value  $0 \leq u_0(x) \leq 1$  for KPP with compact, nonempty support and let  $u(t, x)$  be the solution.

Theorem (Weinberger '02, Beresytcki, Hamel, Nadin '08))

For

$$w(e) = \min_{f \cdot e > 0} \frac{c(f)}{f \cdot e}$$

the following holds

$$\begin{aligned} \lim_{t \rightarrow \infty} u(t, x + wte) &= 0, & x \in \mathbb{R}^n, w > w(e) \\ \lim_{t \rightarrow \infty} u(t, x + wte) &= 1, & x \in \mathbb{R}^n, 0 \leq w < w(e) \end{aligned}$$

$w(e)$  is called the spreading speed in direction  $e$ .

We will see that the formula for  $w(e)$  can be inverted:

$$c(e) = \sup_f (e \cdot f) w(f)$$

# Variational Formulation of the Speed

There exists a variational formulation of  $k(\lambda)$  using the maximum principle:

$$k(\lambda) = \inf_{0 < \phi e^{-\lambda e \cdot x} \in C_{per}^2} \sup_x \frac{(L_\lambda \phi)(x)}{\phi(x)}$$

Difficult to use for qualitative analysis. Seek an integral variational principle.

The adjoint operator of  $L_\lambda$  is

$$(L_\lambda^* \psi) = \nabla(A(x))^T \nabla \psi(x) + \mu(x) \psi(x)$$

$$\psi(x) e^{\lambda e \cdot x} \text{ is 1-periodic}$$

Observe that  $k(\lambda)$  is a critical value of:

$$\int_C (-\nabla \psi A \nabla \phi + \mu \phi \psi) dx \rightarrow \text{critical} \quad \text{with constraint} \quad \int_C \phi \psi dx = 1$$

**Goal:** Transform s.t. convex and concave part are separated:

$$\begin{aligned}\phi(\mathbf{x}) &= \alpha(\mathbf{x})\mathbf{e}^{\lambda\rho(\mathbf{x})}, & \psi(\mathbf{x}) &= \alpha(\mathbf{x})\mathbf{e}^{-\lambda\rho(\mathbf{x})} \\ \alpha(\mathbf{x}), \rho(\mathbf{x}) - \mathbf{e} \cdot \mathbf{x} & \text{ are 1-periodic}\end{aligned}$$

$$G(\alpha, \rho, \lambda) := \int_C \left( -(\nabla\alpha - \lambda\alpha\nabla\rho)\mathbf{A}(\nabla\alpha + \lambda\alpha\nabla\rho) + \mu\alpha^2 \right)$$

$$= \int_C \left( \lambda^2\alpha^2\nabla\rho\mathbf{A}_s\nabla\rho + 2\lambda\alpha\nabla\rho\mathbf{A}_a\nabla\alpha - \nabla\alpha\mathbf{A}_s\nabla\alpha + \mu\alpha^2 \right)$$

$$\rightarrow \text{critical point} \quad \text{with constraint} \quad \int_C \alpha^2 = 1$$

$$\text{where } \mathbf{A}_s := \frac{1}{2}(\mathbf{A} + \mathbf{A}^T), \quad \mathbf{A}_a := \frac{1}{2}(\mathbf{A} - \mathbf{A}^T)$$

Now the following saddle point property for  $k(\lambda)$  follows:

Theorem (Donsker-Varadhan '76, Holland '78)

$$k(\lambda) = \sup_{\alpha} \inf_{\rho} G(\alpha, \rho, \lambda) = \inf_{\rho} \sup_{\alpha} G(\alpha, \rho, \lambda)$$
$$\alpha, \rho - \mathbf{e} \cdot \mathbf{x} \in C_{per}^1(\mathbb{R}^n), \alpha > 0, \int_C \alpha^2 dx = 1$$

The Euler Lagrange equations are:

$$\nabla(\mathbf{A}_s \nabla \alpha) + \lambda^2 \alpha \nabla \rho \mathbf{A}_s \nabla \rho + \lambda \alpha \nabla \cdot \mathbf{A}_a \nabla \rho + \mu \alpha = k(\lambda) \alpha$$

$$\lambda \nabla(\alpha^2 \mathbf{A}_s \nabla \rho) + \nabla \cdot (\mathbf{A}_a \nabla \alpha^2) = 0$$

This is a selfadjoint problem for  $\alpha$  coupled to a Poisson equation for  $\rho$ .

# Saddle point principle for the speed

**Goal:** Eliminate  $\lambda$  in  $c(\mathbf{e}) = \inf_{\lambda > 0} \frac{k(\lambda)}{\lambda}$ .

Idea: Consider

$$J(\alpha, \rho) := \inf_{\lambda > 0} \frac{G(\alpha, \rho, \lambda)}{\lambda}$$

$$= 2 \left( \int_C (\mu \alpha^2 - \nabla \alpha \mathbf{A}_s \nabla \alpha) \int_C \alpha^2 \nabla \rho \mathbf{A}_s \nabla \rho \right)^{1/2} + \int_C \nabla \rho \mathbf{A}_a \nabla \alpha^2,$$

if  $\int_C (\mu \alpha^2 - \nabla \alpha \mathbf{A}_s \nabla \alpha) \geq 0$  and  $-\infty$  otherwise.

Let  $(\alpha_\lambda, \rho_\lambda)$  be the saddle point of  $G(\alpha, \rho, \lambda)$ . and let  $\lambda^* > 0$  be the unique minimizer of  $k(\lambda)/\lambda$ .

Have to show, that  $J(\alpha_{\lambda^*}, \rho_{\lambda^*}) > -\infty$  holds.

This follows from

$$0 = \frac{d}{d\lambda} \frac{k(\lambda)}{\lambda} \Big|_{\lambda^*} = \int_C \alpha_{\lambda^*}^2 \nabla \rho_{\lambda^*} \mathbf{A}_s \nabla \rho_{\lambda^*} - \frac{1}{\lambda^{*2}} \int_C (\mu \alpha_{\lambda^*}^2 - \nabla \alpha_{\lambda^*} \mathbf{A}_s \nabla \alpha_{\lambda^*})$$

Since  $J$  is convex, w.r.t.  $\lambda, \rho$  and concave w.r.t.  $\alpha$  we obtain:

**Theorem: (Saddle point principle)**

$$c(e) = \sup_{\alpha} \inf_{\rho} J(\alpha, \rho) = \inf_{\rho} \sup_{\alpha} J(\alpha, \rho)$$
$$\alpha, \rho - e \cdot x \in C_{per}^1(\mathbb{R}^n), \alpha > 0, \int_C \alpha^2 dx = 1$$

## Dual variational principle

**Goal:** Dualize the infimum into a supremum:

For simplicity assume  $A_a = 0$ .

Let  $v(x)$  be a nontrivial periodic divergence free  $C^1$  vector field.

$$\left( \int_C e \cdot v \right)^2 = \left( \int_C v \nabla \rho \right)^2 \leq \int_C \frac{v A^{-1} v}{\alpha^2} \int_C \alpha^2 \nabla \rho A \nabla \rho$$

and equality holds iff  $v = \gamma \alpha^2 A \nabla \rho$  for some  $\gamma \in R$ . This is the Euler Lagrange equation for  $\rho$ .

**Theorem (Maximization principle)**

$$c(e)^2/4 = \sup_{\alpha, v} \frac{\left( \int_C v \cdot e \right)^2 \int_C (\mu \alpha^2 - \nabla \alpha A \nabla \alpha)}{\int_C \frac{v A^{-1} v}{\alpha^2}}$$

$\alpha, v \in C_{per}^1(R^n), \alpha > 0, \int_C \alpha^2 dx = 1, \nabla \cdot v = 0, v \neq 0$

For  $n = 1$  this simplifies to:

$$c(e)^2/4 = \sup_{\alpha} \frac{\int_0^1 (\mu\alpha^2 - A\alpha'^2)}{\int_0^1 \frac{1}{A\alpha^2}}$$

# Qualitative Consequences

## Smooth Dependence

The principle eigenvalue  $k(\lambda)$  is simple. Hence it depends smoothly on parameters.

One can show that

$$\frac{d}{d\lambda} \frac{k(\lambda)}{\lambda} \Big|_{\lambda^*} = 0 \quad \text{implies} \quad \frac{d^2}{d^2\lambda} \frac{k(\lambda)}{\lambda} \Big|_{\lambda^*} > 0.$$

Hence the minimal speed also depends smoothly on parameters.

Suppose that the functional  $J$  depends on a parameter  $t$  and  $(\alpha_t, \rho_t)$  is the saddle point. Then

$$\frac{d}{dt} c(t) = \partial_t J(\alpha_t, \rho_t, t)$$

## Dependence on the direction

Extend the definition of  $c(e)$  and  $w(e)$  as a homogeneous function to all  $e \in R^n$  of degree 1 and degree -1 respectively.

### Theorem

$c(e)$  and  $w(e)$  satisfy:

1.  $c(e), w(e) > 0, \quad e \neq 0$
2.  $c(se) = sc(e), \quad s \geq 0$
3.  $c(e + f) \leq c(e) + c(f)$
4.  $c(e)$  is the support function of a convex body.
5.  $1/w(e)$  is the support function of the polar convex body,  
i.e.  $1/w(e) = \sup_{f \neq 0} \frac{e \cdot f}{c(f)}$
6.  $c(e) = \sup_{f \neq 0} e \cdot f w(f)$

## Dependence on the period

Consider the symmetric case  $A_a = 0$ .

For  $L > 0$  replace in (KPP)  $A(x)$  and  $f(x, u)$  by  $A(x/L)$  and  $f(x/L, u)$ . A rescaling of  $x$  gives:

$$c(L)^2/4 = \sup_{\alpha} \inf_{\rho} \int_C (\mu \alpha^2 - \frac{1}{L^2} \nabla \alpha A^s \nabla \alpha) \int_C \alpha^2 \nabla \rho A^s \nabla \rho$$

Let  $(\alpha_L, \rho_L)$  be the saddle point of  $J$ .

### Theorem

$$\frac{d}{dL} c(L) = \frac{2}{L^3} \int_C \nabla \alpha_L A \nabla \alpha_L \geq 0$$

*holds. Equality holds for some  $L_0 > 0$  or equivalently for all  $L > 0$  iff*

$$\frac{\int_C \nabla \rho A \nabla \rho}{\int_C \nabla \rho A \nabla \rho} + \frac{\mu}{\int_C \mu} = 2$$

where  $\rho$  solves

$$\nabla(A \nabla \rho) = 0, \quad \rho(x) - e \cdot x \quad \text{is 1-periodic}$$

**Remark:** There exist nonconstant media, s.t. the speed is independent of the period and the direction.  
(test case for numerics)

# Homogenization

For simplicity consider the case  $A_a = 0$  only.

## Theorem

*The following limit exists*

$$\lim_{L \rightarrow 0} c(L) =: c_0 = 2\sqrt{\bar{\mu}eA^he}$$

*and equals the minimal speed of the homogenized equation.*

**Proof:** Choosing  $\alpha = 1$  in the variational principle gives:

$$c(L)^2/4 \geq \int_C \mu \inf_{\rho} \int_C \nabla \rho A \nabla \rho = 2\sqrt{\bar{\mu}eA^he}$$

Let  $(\alpha_L, \rho_L)$  be the critical point of  $J(\alpha, \rho, L)$ . We know:

$$\int_C (\mu \alpha_L^2 - \frac{1}{L^2} \nabla \alpha_L \mathbf{A} \nabla \alpha_L) \geq 0$$

This implies  $\alpha_L \rightarrow 1$  in  $H_{per}^1$ . We have for every  $\rho$ :

$$\begin{aligned} c(L)^2/4 &= J(\alpha_L, \rho_L) \leq J(\alpha_L, \rho) \\ &\leq \int_C \mu \alpha_L^2 \int_C \alpha_L^2 \nabla \rho \mathbf{A} \nabla \rho \rightarrow \int_C \mu \int_C \nabla \rho \mathbf{A} \nabla \rho \end{aligned}$$

Minimizing over  $\rho$  completes the proof.

# Large period limit

## Theorem

Suppose  $A_a = 0$ . Then

$$\lim_{L \rightarrow \infty} c(L) = c_\infty = \sup_{\alpha, v} \frac{(\int_C v \cdot e)^2 \int_C \mu \alpha^2}{\int_C \frac{v A^{-1} v}{\alpha^2}}$$

In 1-D we have  $c_\infty = \sup_{\alpha} \int_0^1 \mu \alpha^2 \left( \int_0^1 \frac{1}{A \alpha^2} \right)^{-1}$

The supremum can be evaluated, conjectured by Hamel, Fayard, Roques '10.

## Theorem

Let  $\mu^* = \sup \mu(x)$  and assume

$$\mu^* \int_0^1 (a(\mu^* - \mu))^{-1/2} \geq 2 \int_0^1 \left( \frac{\mu^* - \mu}{a} \right)^{1/2}$$

Then

$$c_\infty = \inf_{\eta > \mu_+} \frac{\eta}{\int_0^1 \sqrt{\frac{\eta - \mu}{a}}}$$

This holds e.g. if  $\mu$  is piecewise  $C^2$ . If  $\mu$  is constant this gives

$$c_\infty = 2\sqrt{\mu} \left( \int_0^1 \frac{1}{\sqrt{a}} \right)^{-1}$$

**Proof:** The lower is obtained by choosing  $\alpha = (a(\eta - \mu))^{1/4}$  in the variational principle and maximizing over  $\eta$ .

The upper bound follows from

$$\left( \int_C \sqrt{\frac{\psi - \mu}{a}} \right)^2 \leq \int \alpha^2 (\eta - \mu) \int_C \frac{1}{a\alpha^2}$$

and minimizing over  $\eta$ . Equality of these bounds holds iff the condition above holds.

# Dependence on $\mu$

## Theorem

If  $A$  is constant, then  $\mu \mapsto \gamma(\mu) := c(\mu)^2$  is increasing and convex.

In particular if  $\mu_2(x) = \mu_1(x + a)$  holds, then

$$c\left(\frac{\mu_1 + \mu_2}{2}\right) \leq c(\mu_1)$$

follows, i.e. fragmentation decreases the minimal speed.

**Proof:** Let  $(\alpha, \nu)$  be the maximizer of  $J^*(\alpha, \nu, (\mu_1 + \mu_2)/2)$  where  $J^*$  is the functional of the dual variational principle.

$$\begin{aligned} c\left(\frac{\mu_1 + \mu_2}{2}\right)^2 &= J(\alpha, \nu, \frac{\mu_1 + \mu_2}{2})^2 \\ &= \frac{1}{2} J(\alpha, \nu, \mu_1)^2 + \frac{1}{2} J(\alpha, \nu, \mu_2)^2 \leq \frac{c(\mu_1)^2 + c(\mu_2)^2}{2} \end{aligned}$$

# Optimization over $\mu$

## Theorem

Suppose that  $A$  is constant and let  $\bar{\mu} > 0$  be given. Then

$$\sup_{\int_0^1 \mu = \bar{\mu}} c(\mu) = c(\bar{\mu} \delta_{x_0})$$

where  $\delta_{x_0}$  is the Dirac functional at  $x_0$ .

In 1-D this is finite.

**Proof:** The convexity implies for every periodic  $\nu$  with integral one:

$$c(\mu * \nu) \leq c(\mu)$$

The variational formula can be extended to measures.

Choosing  $\mu = \bar{\mu} \delta_{x_0}$  completes the proof.

Related rearrangement results: Nadim (2010)

# Generalizations

- ▶ Less regular data  $A, f, \mu$ , e.g.  $\mu$  could be a characteristic function.
- ▶  $f(x, u) < 0$  for  $u > M$  instead of  $f(x, 1) = 0$ . Then  $U^+(x)$  is a periodic function instead of  $U^+ = 1$ .
- ▶ Instead of  $\mu(x) \geq 0$ , assume  $k(0) > 0$ , e.g.  $\int_C \mu > 0$  is enough.
- ▶ Perforated domains.
- ▶ Space and time periodic data.
